

TradeAlerts Simulation Overview

Next-Generation Indicators

The TradeAlerts platform includes advanced, configurable technical filters that go beyond traditional indicators. These 'Next-Generation' indicators are used to refine high-confidence trade entry signals. Here are their definitions:

RSI Slope > 0:

This filter ensures the Relative Strength Index (RSI) is rising. RSI Slope is calculated as the first derivative (difference) between the most recent two RSI values. A positive slope indicates increasing bullish momentum.

MACD Histogram > 0.5:

The MACD histogram measures the distance between the MACD line and the signal line. When the histogram exceeds 0.5, it signals strong upward momentum beyond typical crossovers.

Bollinger Band Breakout:

A breakout is defined when the current price closes above the upper Bollinger Band. This is often used as a signal of bullish continuation or explosive breakout strength.

ATR (Average True Range) >= 1.4:

ATR is a volatility indicator. A high ATR value suggests active price movement. This filter ensures only stocks with meaningful daily price movement are considered.

ATR % >= 0.7%:

This relative volatility filter compares ATR against current price to normalize across different stock price ranges. A value >= 0.7% ensures we focus on relatively volatile stocks.

Range % >= 1.2%:

Range is defined as the percentage difference between the high and low of the current candle. This ensures sufficient intraday movement to justify entry.

TradeAlerts Simulation Overview

Gap % $\geq$ 1.0%:

Measures the gap between the previous day's close and today's open. A gap of $\geq$ 1.0% may signal market sentiment or news-based momentum.

These filters can be toggled on or off individually from the dashboard, allowing precise control over the signal quality and risk-reward balance.
